ABSTRACT OF THE DISCLOSURE

A system and method for securing pathways to a remote application server involves a gateway or authentication server, and a mobile code authentication and encryption client available for download from the gateway Upon connection of authentication server. computing device to the authentication server over the authentication network, the server requests open authentication information, such as a password, from the upon authentication of the user user, and by authentication server, the authentication server downloads the mobile code authentication and encryption client to the user's computing device. The authentication and encryption client then authenticates itself to authentication server, after which a secure communications channel between the user's computing device and the authentication server is opened, secure communications channel permitting the transfer of data between the user's computing device and an application server. The system and method do not require certificates pre-installation orany or authentication and encryption software on the user's computing device, enabling the system and method to be used with thin-client and mobile computing devices, as well as with conventional computers.
